**Urine Sediment Guide**

**Specific Gravity:** The urine specific gravity should be measured with a refractometer, which measures the density of the urine relative to the density of water. This value should be interpreted in light of the patient's hydration status and serum blood urea nitrogen (BUN) and creatinine levels.

**Leukocytes:** The leukocyte test pad detects the enzyme leukocyte esterase, not individual leukocytes. Evaluation of urine leukocytes must be confirmed by urine microscopic examination. The sensitivity and specificity of the leukocyte esterase test pad is questionable in veterinary medicine, especially in cat urine.

**Protein:** While small amounts of protein may normally be found in the urine, proteinuria can indicate both renal and nonrenal disease. If significant proteinuria is detected and there is an inactive sediment, urine protein:creatinine ratio (UPC) should be performed for protein quantification and monitoring.

**Ketones:** Urine ketones are produced by the breakdown of lipids. Causes for elevations include diabetic ketoacidosis, prolonged fasting, starvation and low-carbohydrate diets.

**Bilirubin:** In dogs (especially male dogs) bilirubinuria is common even under normal conditions, but any bilirubinuria in cats is significant. Bilirubinuria usually precedes bilirubinemia because urine is commonly concentrated (hypersthenuric) compared to plasma.

**pH:** Urine pH is determined by the kidney's ability to regulate hydrogen ion and bicarbonate concentrations within the body. Urine pH may reflect the animal's acid-base status. Proteinuria and overall plasma electrolyte balance are not markedly disturbed.

**Nitrite:** The nitrite test is not valid for veterinary use. The majority of bacterial infections in dogs and cats are not caused by organisms that reduce nitrate to nitrite. Both false positive and false negative results are common in veterinary medicine, making it too insensitive for general use.

**Glucose:** Glucose is not usually detectable in the urine of dogs and cats, but any bilirubinuria in cats is significant. Bilirubinuria usually precedes bilirubinemia because urine is commonly concentrated (hypersthenuric) compared to plasma.

**Urobilinogen:** Intestinal bacteria convert conjugated bilirubin to urobilinogen. A freshly produced urine sample is necessary for evaluation. The correlation between increases or decreases of urine urobilinogen and liver disease in animals is poor.

**Blood:** The blood/heme reaction detects heme groups found within hemoglobin and myoglobin. The test may be positive because of hematuria, hemoglobinuria or myoglobinuria.

**Compensation Pad:** This white pad, which is not impregnated with reagents, is used by the IDEXX VetLab UA Analyzer to compensate for the intense intrinsic color of the urine that might affect the evaluation of the parameters for leukocytes, protein, glucose, ketone bodies, urobilinogen and bilirubin.
